**Note:** Answer Any Five Questions

| Question |    | Description   | Mar       | Max     |      |
|----------|----|---|-----------|---------|------|
| #        |    |   | Distrib   | Marks   |      |
| 1        | a) | List out and explain the protective devices in residential electrical installation.  • List of all the protective devices used • Elaborate any 4 (each 2 marks)  RESIDUAL CURRENT CIRCUIT BREAKER  RCCB is provided mainly for the protection of human being from accidental electric shock that can occur due to faulty wiring or earth faults. In normal working conditions of the circuit the current flowing into it through the live wire is same as that of the current coming out the neutral wire.IN case of an earth fault the current finds path to earth. For example a person comes into accidental contacts with live wire then current flows to earth and the amount of current returning through the neutral is reduced and this reduced current is known as residual current. The RCCB continuously monitors the amount of current flowing and if there is any difference in current detected then it trip out.  TEST PUSHBUTTON  TEST PUSHBUTTON  TEST RESISTOR  SEARCH  SEARCH  A torroidal transformer is contained within the RCCB body this helps to detect the current imbalance within the system. There is current path for live and neutral wires connected to the transformer. A magnetic flux is generated proportional to the current drawn through the live and neutral wire. The construction of windings is such that they produce magnetic fields in the opposite direction. Net magnetic flux is zero in the case when there are no faults, since the magnetic flux will be greater than zero which will result in the tripping of circuit to avoid accidental shocks. | 2 M<br>8M | 10<br>M | 10 M |

There are two types of RCCB

#### TWO POLE RCCB

Two pole RCCB is used in case of a single phase supply. It has two points to which a live wire and neutral wire is connected.

# FOUR POLE RCCB

Four pole RCCB is used in case of 3 phase supply. It has 2 ends to which 3 phase wires and one neutral wire is connected.

#### MINIATURE CIRCUIT BREAKER

There is a bi-metallic strip which becomes over heated when circuit is overloaded for long time. Overheating results in deformation of the strip and causes displacement of latch point. Even a slight movement of latch causes release of spring and makes the moving contact to move for opening the MCB. During short circuit the MMF of current coil causes its plunger to hit the latch point and displaces the latch, which results in the opening of the MCB. Arc generated by high currents will reach the arching chamber through the guide plate. The arc is separated into smaller arcs by the arc splitter and extinguished there.

# CLASSIFICATION OF MCB BASED ON TRIPPING CHARACTERISTICS TYPE B

These are mainly used for residential purpose. They trip between 3 and 5 times full load current.

#### TYPE C

This type of MCB is used where there can be chances of higher values of short circuit current in the circuit like commercial or industrial type of application. Loads connected are mainly inductive in nature. They trips between 5 and 10 times full load current.

## TYPE D

This type of MCB is used for commercial purposes where there is high current in flow. They trip between 10 and 20 times full load current. RCCB, MCB, fuses, ELCB, are all devices used to protect users and equipment from fault conditions in an electrical circuit by isolating the electrical supply. **Fuses** 

Fuse is a protection device which melts and breaks the circuit when the current rating exceeds the rating of the fuse. Fuse must be replaced ones it has melted. Fuses are becoming rare as electrical installations are updated.

#### **ISOLATORS**

Electrical isolators isolates a part of the system from rest this is useful when circuit breaker trip the circuit but the open contacts are not visible from the outside so it's not safe to touch the circuit just by switching of the circuit breaker. Therefore the isolator is opened only after the circuit breaker is opened and closed before the circuit breaker is closed. Electrical isolators must be operated only when there is no current flowing through the circuit. Isolator can be operated by hand as well as by motorized setup. But motorized set up costs more than hand operation.

# TYPES OF ISOLATORS

# DOUBLE-BREAK ISOLATOR

There are three post insulators. The central post insulator can be rotated. There is a flat male contact on central post insulator which rotates as central post insulator rotates. Female contacts are fixed up

on the other two post insulators.

The rotating movement of male contact makes it in contact with the female contact and isolator becomes closed. And as the isolator rotates in opposite direction it loses the contact with female contact and isolator becomes open. Driving lever mechanism enables rotation of the central post insulator.

# SINGLE- BREAK ISOLATOR

There are two post insulators which rotate. And due to their rotation the male and the female contacts fitted over them also rotates. Rotation of both post insulators stacks in opposite direction causes to close the isolator by closing the contact arm. Counter rotation of both post insulators stacks open the contact arm and isolator becomes in off condition.

Isolators are classified depending upon their position in power system.

- 1-Line side isolator is at the line side of any feeder.
- 2-Bus side isolator is directly connected with the main bus.
- 3-Transfer bus side isolator is directly connected with transfer bus.

# **RCBO** (Residual Current Breaker with Overcurrent)

When there is need of combined protection against over current (over load and short circuit) and protection against earth leakage current RCBO is used.

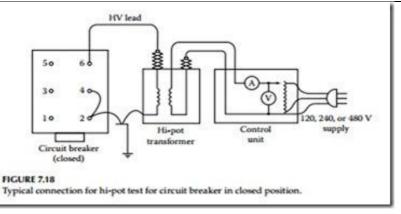

It has wide range of breaking capacities and can be used for industrial and residential purposes.it has the combined effect of MCB and RCCB in one device. Every circuit has its own RCBO therefore if any device is tripped due to residual current, only the faulty circuit is disconnected.

The internal residual current detecting element will trip the circuit when there is a current leakage fault. The internal thermal/magnetic circuit breaker parts are able to trip the device when the circuit is over loaded. RCBO come in single pole and dual pole variations. The single pole is used as a direct replacement for MCB.

## ELCB

An ELCB is a voltage sensing device which is used to prevent shock threats as well as protection of instruments. Earlier it was widely used but now a days RCCB's are in use for protection. An ELCB has a relay coil one of the terminals is connected to the equipment and other terminal is given to ground directly. In case of faulty conditions like if insulation of the equipment fails or live phase wires touches the metal part of the equipment, a voltage difference appears across the coil which is connected to device and earth. After this voltage reaches a limit, current developed in the relay trips the circuit breaker and the power supply to the device is stopped.

|   |    | Load Relay   |            |         |      |

|   |    | 2. With breaker open:  |            |         |      |
|   |    | - Between R, Y, B phases shorted together (on bus-bar side )and the frame of the CB.   |            |         |      |
|   |    | - Between 1 terminal of each pole & other terminal of same pole connected to the frame of CB   |            |         |      |

#### Impulse voltage test/ Power frequency voltage withstand tests

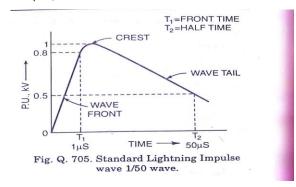

- ➤ Impulse wave of specified amplitude is applied five times in succession(+&-ve polarity)
- Impulse generator
- > Test voltage applied across each pole and earth for one minute.
- The peak value of the impulse wave and its shape is recorded using CRO with calibrated voltage divider

# Impulse Voltage characterised by

- · Polarity
- Peak value
- · Virtual front
- Virtual half time/Wave Tail

Standard lightning impulse (1.2/50 µsec)

Switching impulse(250/2500 µsec)

# **Temperature Rise Test**

- ☐ Rated ac voltage at rated frequency passes continously
- keep the contacts in the closed position.
- Readings of various conducting, Insulating and structural parts are taken at an interval of one or half an hour.
- ☐ When steady temperature is reached the maximum temperature rise of each part should be less than the permitted values.

## **Mechanical Test (Endurance Test)**

- > The breaker should consistently open and close its contacts(nearly 1000 times).
- During the test, test is done without charging the main circuit.
- Adjustment or replacement of any part of the circuit breaker is not allowed.
- ➤ Lubricate as per the instructions of the manufacturer
- The tests are to be conducted after the improvement in the design and manufacture.

- After the Mechanical Endurance test,
- Contacts and other parts of circuit breaker must be in good position and there should not be any permanent deformation of any parts.
- Test proves the adequacy of design and also good quality of material used in manufacture.

#### **Test for Contact Resistance of Circuit Breaker Pole**

- ☐ Routine test at ambient temperature.
- $\label{eq:Rpole} \blacksquare \quad R_{POLE} < m^*20 \; \mu\Omega$
- m is the number of joints, contacts in series per pole.
- This is measured by two methods.
  - 1. Micro ohmmeter:
  - 2. Millivolt drop method: The voltage drop across the circuit breaker pole is measured for different values of dc current.

The dc current should be sufficiently high but must be less than the rated current.

#### **Time Versus Travel Characteristics**

A travel trace is drawn showing the movement of the linkage

- · Contact opening speed.
- Total distance of contact travel.
- See any type of binding to the linkage affecting travel or opening speed.

#### 1. Use of potentiometer

- ☐ the two fixed terminals of potentiometer 3 volts dc.
- The stem connected to the variable terminal of the potentiometer is connected to the lever of the circuit breaker.
- ☐ As the lever moves during opening and closing operation, generates a potential through the variable terminal changes proportional to the travel.
- ☐ Ultraviolet recorder

#### Short Circuit Test set up

- > To prove the ratings and the behaviour of the CB
- Master CB
- Making switch
- Series resistors and reactors
- short circuit generators.
- three phase induction motors
- > In addition, Measurement, record control, sequential operation, Auxiliaries, Transformers

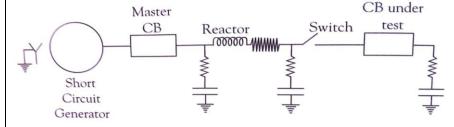

Figure 4.4: Layout of a simple short circuit test station

The circuit breaker should be capable of performing the opening and closing operations as per **rated operating sequence** for all values of short circuit currents upto its rated short circuit breaking current at specified test voltage and relevant conditions of transient recovery voltage for terminal short circuits.

# Pulse Echo Method

- Helps to pin point the fault location accurately
- Test setup: Transmitter (LVHF Pulse), Time domain Oscilloscope
- Test pulse is transmitted
- Pulse Reflected back at fault
- Transmitted pulse and reflected pulse analysed in oscilograph

D = Vt/2

- o D = Distance Btw Test location and fault location
- o V = Velocity of propagation
- $\circ$  t = Transit Time

# Murray loop method - bridge method

Only for short circuit faults
Used only when one healthy conductor is

available 
$$\frac{R_1}{R_2} = \frac{R_g + R_y}{R_x}$$

Or 
$$\frac{R_1}{R_2} + 1 = \frac{R_g + R_v}{R_x} + 1$$

Or 
$$\frac{R_1 + R_2}{R_2} = \frac{R_g + R_y + R_x}{R_z}$$

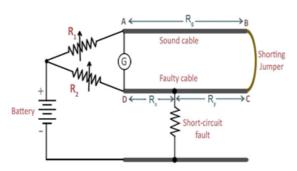

fig.(i) Murray loop test for short-circuit fault

$$\frac{R_{1}}{R_{2}} = \frac{R_{g} + R_{v}}{R_{x}}$$
Or 
$$\frac{R_{1}}{R_{2}} + 1 = \frac{R_{g} + R_{v}}{R_{x}} + 1$$

Or  $\frac{R_1 + R_2}{R_2} = \frac{R_g + R_v + R_x}{R_x}$ 

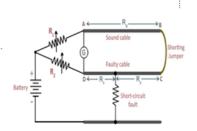

fig.(i) Murray loop test for short-circuit fault

Now, if r is the resistance of each cable, then,  $R_x + R_y + R_g = 2r$ 

Putting this in the above equation,

$$\frac{R_1 + R_2}{R_2} = \frac{2r}{R_x}$$

$$R_x = \frac{R_2}{R_1 + R_2} \times 2r$$

Only for short circuit faults

$$L_x = \frac{R_2}{R_1 + R_2} \times 2L$$

#### 1. Oil Circuit Breakers

In oil type of circuit breakers, some insulating oil (in, transformer oil) is used as an arc quenching medium.

The contacts are opened under oil and an arc is struck between them. The heat of the arc evaporates the surrounding oil and dissociates it into a substantial volume of gaseous hydrogen at high pressure.

The hydrogen gas occupies a volume about one thousand times that of the oil decomposed. The oil is, therefore, pushed away from the arc and an expanding **hydrogen gas bubble** surrounds the arc region and adjacent portion of the contacts. The arc extinction is facilitated mainly by two processes.

Firstly, the **hydrogen gas** has high heat conductivity and cools the arc, thus aiding the de-ionization of the medium between the contacts. Secondly, the gas set up **turbulence** in the oil and forces it into the space between contacts, thus eliminating the arcing products from the arc path. The result is that arc is extinguished and circle current interrupted.

#### 2. Air-Blast Circuit Breakers

These type of circuit breakers employ a **high-pressure air-blast** as a quenching medium. The contacts are opened in a flow of air-blast established by the opening of the blast valve. The air-blast cools the arc and sweeps away the arcing products to the atmosphere. This rapidly increases the dielectric strength of the medium between contacts and prevents from re-establishing the arc. Consequently, the arc is extinguished and the flow of current is interrupted.

# 3. Sulphur Hexafluoride SF6 Circuit Breaker

In such type of circuit breakers, sulphur hexafluoride (SF6) gas is used as the arc quenching medium.

The SF6 is an electronegative gas and has a strong tendency to absorb free electrons. The contacts of the breaker are opened in a high-pressure flow of SF6 gas and an arc is struck between them. The conducting free electrons in the arc are rapidly captured by the gas to form relatively immobile negative ions. This loss of conducting electrons in the are quickly builds enough insulation strength to extinguish the arc. The SF6 circuit breakers have been

#### 4. Vacuum Circuit Breakers (VCB)

found to be very effective for high power and high voltage service.

In such type of circuit breakers, vacuum (degree of vacuum being in the range from 10 to 10 torr) is used as the are quenching medium. Since vacuum offers the highest insulating strength, it has far superior are quenching properties than any other medium. For example, when contacts of a breaker are opened in vacuum the interruption occurs at first current zero with dielectric strength between the contacts building up at a rate thousands of times higher than that obtained with other circuit breakers.

|   |    | Principle of VCB  |            |         |      |
|---|----|---|------------|---------|------|
|   |    |   |            |         |      |
|   |    | The arc formation in a vacuum circuit breaker and its extinction can be explained as follows:   |            |         |      |
|   |    | When the contacts of the breaker are opened in a vacuum (10 to 10 tor), an arc is produced between the contacts   |            |         |      |
|   |    | by the ionization of metal vapors of contacts. However, the arc is quickly extinguished because the metallic  |            |         |      |
|   |    | vapours, electrons, and ions produced during arc rapidly condense on the surfaces of the circuit breaker contacts,  |            |         |      |
|   |    | resulting in quick recovery dielectric strength.  |            |         |      |
|   | a) | Explain the radar method of locating cable fault.   |            |         |      |
|   |    | Circuit diagram   |            |         |      |

|   |    | Pulse Echo Method   |            |         |      |
| 7 |    | The pulse echo technique is performed with a time domain reflectometer (TDR), which combines a transmitter and a receiver. The transmitter sends out a low voltage high frequency pulse of a short duration onto a cable. This pulse of energy travels along the surface of the cable until it encounters some type of disruption manifested in a change within the characteristic impedance of the cable; these mismatches in the characteristic impedance of the cable may be caused by the start of the cable, splices in the cable, transformers, faults, etc. Depending upon the magnitude of the impedance change, either part or all of the transmitted energy reflects and travels back to the time domain reflectometer. In essence, this technique creates an electronic or a graphical roadmap of the underground cable showing different events along that path.  • Helps to pin point the fault location accurately  • Test setup: Transmitter (LVHF Pulse), Time domain Oscilloscope / reflectometer.  • Test pulse is transmitted  • Pulse Reflected back at fault  • Transmitted pulse and reflected pulse analysed in oscilograph  D= Vt/2  o D = Distance Btw Test location and fault location  o V = Velocity of propagation  o t = Transit Time | 3 M<br>7 M | 10<br>M | 10 M |
