## Internal Assessment Test 3 – Jan. 2022

Sub:	ARTIFICIAL INTELLIGENCE AND MACHINE LEARNING	Sub Code:	18CS71	Branch:	CSE		
Date:	24/01/2022 Duration: 90 mins Max Marks: 50	Sem / Sec:	7/2	A,B,C		OE	BE
	Answer any FIVE FULL Questions				ARKS		RBT
1 a)	Derive an equation for maximum a posteriori(MAP) hytheorem. Ans: Using Bayes theorem	ypothesis us	sing Bayes		[5]	CO2	L2
	$P(h D) = \frac{P(D h)P(h)}{P(D)}$						
	Generally want the most probable hypoth the training data	esis giver	1				
	Maximum a posteriori hypothesis $h_{MAP}$ :						
	$h_{MAP} = \arg \max_{h \in H} P(h D)$ $= \arg \max_{h \in H} \frac{P(D h)P(h)}{P(D)}$ $= \arg \max_{h \in H} P(D h)P(h)$						
	P(D) is constant ,it can be safely dropped						
1b	Explain naïve bayes classifier  Ans:  Bayesian Classifiers  Consider each attribute and class label as random variables  Given a record with attributes (A <sub>1</sub> , A <sub>2</sub> ,,A <sub>n</sub> )  Goal is to predict class C				[5]	CO3	L2
	<ul> <li>Specifically, we want to find the value of C that maximizes P(C A<sub>1</sub>,A<sub>2</sub>,,A<sub>n</sub>)</li> <li>Approach:</li> <li>compute the posterior probability P(C A<sub>1</sub>,A<sub>2</sub>,,A<sub>n</sub>) for all values of C using the Bayes theorem</li> </ul> P(C AA <sub>1</sub> A <sub>n</sub> ) = P(A <sub>1</sub> A <sub>2</sub> A <sub>n</sub>  C)P(C) P(A <sub>1</sub> A <sub>2</sub> A <sub>n</sub> )						
	<ul> <li>Choose value of C that maximizes</li> <li>P(C   A<sub>1</sub>, A<sub>2</sub>,, A<sub>n</sub>)</li> </ul>						
	Equivalent to choosing value of C that maximizes $P(A_1, A_2,, A_n   C) P(C)$						
	- Assume independence among attributes $A_i$ when class is given: $P(A_1, A_2,, A_n   C) = P(A_1   C_j) P(A_2   C_j) P(A_n   C_j)$						
	$^{\circ}$ Can estimate P(A <sub>i</sub>   C <sub>j</sub> ) for all A <sub>i</sub> and C <sub>j</sub> .						
	• New point is classified to $C_i$ if $P(C_i) \coprod P(A_i \mid C_j)$ is	maximal.					

2 Explain Bayesian belief networks and conditional independence with an example	[10]	CO3	L2
<b>Definition:</b> $X$ is conditionally independent of $Y$ given $Z$ if the probability distribution governing $X$ is independent of the value of $Y$ given the value of $Z$ ; that is, if $(\forall x_i, y_i, z_k) P(X = x_i   Y = y_i, Z = z_k) = P(X = x_i   Z = z_k)$			
more compactly, we write			
P(X Y,Z) = P(X Z)			
Example: $Thunder$ is conditionally independent of $Rain$ , given $Lightning$			
P(Thunder Rain, Lightning) = P(Thunder Lightning)			
Naive Bayes uses cond. indep. to justify			
P(X, Y Z) = P(X Y, Z)P(Y Z) = $P(X Z)P(Y Z)$			
Storm  BusTourGroup  S,B S,-B -S,B -S,-B C 0.4 0.1 0.8 0.2 -C 0.6 0.9 0.2 0.8  Campfire  Network represents a set of conditional independence assertions:			
<ul> <li>Each node is asserted to be conditionally independent of its nondescendants, given its immediate predecessors.</li> </ul>			
Directed acyclic graph	[05]	CO3	L3

3 (b) Explain EM	algorithm					[5]	CO2	L2
$h = \langle \mu_1, \mu_2 \rangle$ • It then it following	<ul> <li>EM algorithm picks two random values as intial means         h = ⟨μ1, μ2⟩</li> <li>It then iteratively re-estimates h by repeating the         following two steps until the procedure converges to a         stationary value for h.</li> </ul>							
• Iter	ate th	e fol	lowing	two s	teps			
E step	E step: Calculate the expected value $E[z_{ij}]$ of each hidden variable $z_{ij}$ , assuming the current hypothesis $h = \langle \mu_1, \mu_2 \rangle$ holds. $E[z_{ij}] = \frac{p(x = x_i   \mu = \mu_j)}{\sum_{n=1}^2 p(x = x_i   \mu = \mu_n)}$ $= \frac{e^{-\frac{1}{2\sigma^2}(x_i - \mu_j)^2}}{\sum_{n=1}^2 e^{-\frac{1}{2\sigma^2}(x_i - \mu_n)^2}}$							
M step	$h' = \langle \mu'_1 $ each hid	$,\mu_2'\rangle,  ext{ as } $ lden var alculated $,\mu_2'\rangle. $	$ \frac{1}{2} \sin i \beta \sin i \beta $ suming the	e value ta its expeceplace $h$				

Ans: Instance based learner is a lazy learner. It Simply stores training data (or only minor processing) and waits until it is given a test tuple. Lazy learners take less time in training but more time in predicting. Lazy method effectively uses a richer hypothesis space since it uses many local linear functions to form an implicit global approximation to the target function.  K-nearest neighbor is an instance-based learning algorithm. It assumes all instances correspond to points in the n-dimensional space. The nearest neighbors of an instance are defined in terms of the standard Euclidean distance.  Training algorithm:  • For each training example $(x, f(x))$ , add the example to the list training_examples  Classification algorithm:  • Given a query instance $x_0$ to be classified,  • Let $x_1 \dots x_k$ denote the $k$ instances from training_examples that are nearest to $x_0$ • Return $\hat{f}(x_0) \leftarrow \underset{x \in V}{\operatorname{argmax}} \sum_{i=1}^{k} \delta(u, f(x_i))$ where $\delta(a, b) = 1$ if $a = b$ and where $\delta(a, b) = 0$ otherwise.  5 Explain locally weighted linear regression  Ans:  Locally weighted regression constructs an explicit approximation to target function f over a local region surrounding $x$ . It uses nearby or distance-weighted training examples to form this local approximation to f. The general regression algorithm chooses weights that minimize the squared error summed over the set D of training examples. In local regression, we normally assign different weights for the error from each training example. There are three popular methods to assign weights. They are  1. Minimize the squared error over just the $k$ nearest neighbors: $E_1(x_0) = \frac{1}{2} \sum_{x \in k \text{ nearest neighbors};$ $E_2(x_0) = \frac{1}{2} \sum_{x \in k \text{ nearest neighbors};$ $E_2(x_0) = \frac{1}{2} \sum_{x \in k \text{ nearest neighbors};$ $E_3(x_0) = \frac{1}{2} \sum_{x \in k \text{ nearest neighbors};$ $E_3(x_0) = \frac{1}{2} \sum_{x \in k \text{ nearest neighbors};$ $E_3(x_0) = \frac{1}{2} \sum_{x \in k \text{ nearest neighbors};$ 1. Combine 1 and 2: $E_3(x_0) = \frac{1}{2} \sum_{x \in k \text{ nearest neighbors};$

In local regression, we normally assign different weights for the error from each training example. There are three popular methods to assign weights.  They are  1. Minimize the squared error over just the $k$ nearest neighbors: $E_1(x_q) \equiv \frac{1}{2} \sum_{x \in k} \sum_{neuv \in x \mid nbrx \mid of x_q} (f(x) - \hat{f}(x))^2$ 2. Minimize the squared error over the entire set $f$ of training examples, while weighting the error of each training example by some decreasing function $f$ of its distance from $f$ is distance from $f$ is distance from $f$ is $f$ in the squared error $f$ in the squared error over the entire set $f$ of training examples, while weighting the error of each training example by some decreasing function $f$ of its distance from $f$ in the squared error over the entire set $f$ is distance from $f$ in the squared error over the entire set $f$ is distance from $f$ in the squared error over the entire set $f$ is distance from $f$ in the squared error $f$ in the squared error $f$ is $f$ in the squared error $f$ in the squared error $f$ in the squared error $f$ is $f$ in the squared error $f$					
Training algorithm:  • For each training example $(x, f(x))$ , add the example to the list training examples  Classification algorithm:  • Given a query instance $x_q$ to be classified,  • Let $x_1 \dots x_k$ denote the $k$ instances from training examples that are nearest to $x_q$ • Return $\hat{f}(x_q) \leftarrow \underset{v \in V}{\operatorname{argmax}} \sum_{i=1}^k \delta(v, f(x_i))$ where $\delta(a, b) = 1$ if $a = b$ and where $\delta(a, b) = 0$ otherwise.  5 Explain locally weighted linear regression  [10] Co3  Ans:  Locally weighted regression constructs an explicit approximation to target function $f$ over a local region surrounding $x$ . It uses nearby or distance-weighted training examples to form this local approximation to $f$ . The general regression algorithm chooses weights that minimize the squared error summed over the set $D$ of training examples. In local regression, we normally assign different weights for the error from each training example. There are three popular methods to assign weights. They are  1. Minimize the squared error over just the $k$ nearest neighbors: $E_1(x_q) \equiv \frac{1}{2} \sum_{x \in k} \sum_{neuv \in x} \inf_{nex \in x} \int_{x_q} (f(x) - \hat{f}(x))^2$ 2. Minimize the squared error over the entire set $D$ of training examples, while weighting the error of each training example by some decreasing function $K$ of its distance from $x_q$ : $E_2(x_q) \equiv \frac{1}{2} \sum_{x \in k} \int_{neuv \in x} f(x) - \hat{f}(x)^2 K(d(x_q, x))$ 3. Combine 1 and 2: $E_3(x_q) \equiv \frac{1}{2} \sum_{x \in k} \int_{neuv \in x} f(x) - \hat{f}(x)^2 K(d(x_q, x))$

Write short notes on Radial Basis Function Case based reasoning

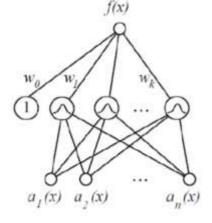

6

[5+5]

Ans: a) Learning with radial basis functions is an approach to function approximation that is closely related to distance weighted regression and also to artificial neural networks. In this approach, the learned hypothesis is a function of the form

$$\hat{f}(x) = w_0 + \sum_{u=1}^{k} w_u K_u(d(x_u, x))$$

A typical radial basis network has the architecture shown below

b) Case based reasoning

Case-based reasoning (CBR) is an instance based learning method that uses the principle of lazy learning. In CBR, instances are typicaly represented using rich symbolic descriptions. CBR has been applied to problems such as conceptual design of mechanical devices based on a stored library of previous designs. In CADET system which is a CBR system, each instance stored in memory (e.g., a water pipe) is represented by describing both its structure and its qualitative function. New design problems are then presented by specifying the desired function and requesting the corresponding structure.
