|---|--|------|-----|----|
| 1 | What are the elements of one M2M architecture of IOT? Explain. | [10] | CO1 | L2 |
|---|--|------|-----|----|

The oneM2M IoT Standardized Architecture

In an effort to standardize the rapidly growing field of machine-to-machine (M2M) communications, the European Telecommunications Standards Institute (ETSI) created the M2M Technical Committee in 2008. The goal of this committee was to create a common architecture that would help accelerate the adoption of M2M applications and devices. Over time, the scope has expanded to include the Internet of Things. One of the greatest challenges in designing an IoT architecture is dealing with the heterogeneity of devices, software, and access methods. By developing a horizontal platform architecture, oneM2M is developing standards that allow interoperability at all levels of the IoT stack

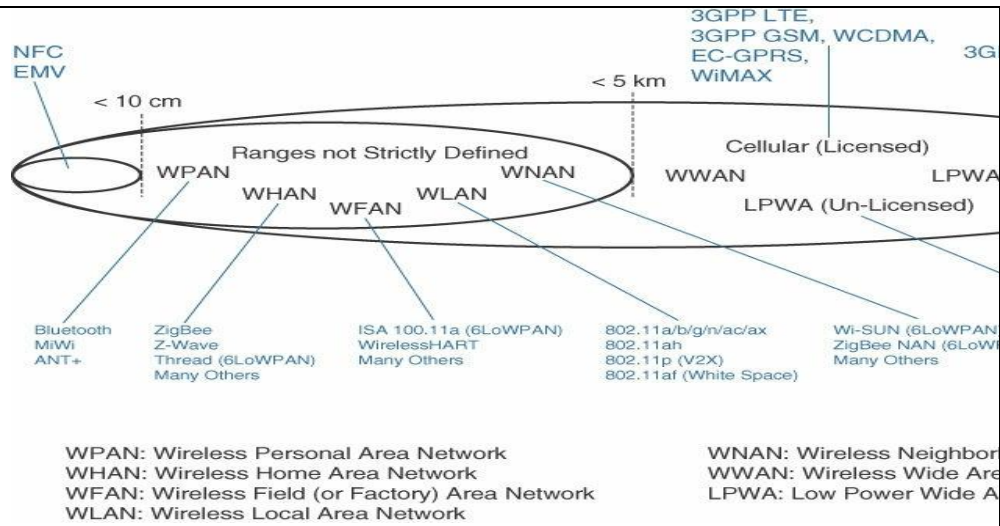

The oneM2M architecture divides IoT functions into three major domains: the application layer, the services layer, and the network layer

Applications layer: The oneM2M architecture gives major attention to connectivity between devices and their applications. This domain includes the application-layer protocols and attempts to standardize northbound API definitions for interaction with business intelligence (BI) systems. Applications tend to be industry-specific and have their own sets of data models, and thus they are shown as vertical entities.

? **Services layer:** This layer is shown as a horizontal framework across the vertical industry applications. At this layer, horizontal

| | <p>modules include the physical network that the IoT applications run on, the underlying management protocols, and the hardware. Examples include backhaul communications via cellular, MPLS networks, VPNs, and so on. Riding on top is the common services layer.</p> <p>Network layer: This is the communication domain for the IoT devices and endpoints. It includes the devices themselves and the communications network that links them. Embodiments of this communications infrastructure include wireless mesh technologies, such as IEEE 802.15.4, and wireless point-to-multipoint systems, such as IEEE 801.11ah. Also included are wired device connections, such as IEEE 1901 power line communications.</p> | | | | | | | | | |

|---|---|------|-----|----|
| | <p>Privacy As sensors become more prolific in our everyday lives, much of the data they gather will be specific to individuals and their activities. This data can range from health information to shopping patterns and transactions at a retail establishment. For businesses, this data has monetary value. Organizations are now discussing who owns this data and how individuals can control whether it is shared and with whom.</p> <hr/> <p>Big data and data analytics IoT and its large number of sensors is going to trigger a deluge of data that must be handled. This data will provide critical information and insights if it can be processed in an efficient manner. The challenge, however, is evaluating massive amounts of data arriving from different sources in various forms and doing so in a timely manner. See Chapter 7 for more information on IoT and the challenges it faces from a big data perspective.</p> <hr/> <p>Interoperability As with any other nascent technology, various protocols and architectures are jockeying for market share and standardization within IoT. Some of these protocols and architectures are based on proprietary elements, and others are open. Recent IoT standards are helping minimize this problem, but there are often various protocols and implementations available for IoT networks. The prominent protocols and architectures—especially open, standards-based implementations—are the subject of this book. For more information on IoT architectures, see Chapter 2, “IoT Network Architecture and Design.” Chapter 4, “Connecting Smart Objects,” Chapter 5, “IP as the IoT Network Layer,” and Chapter 6, “Application Protocols for IoT,” take a more in-depth look at the protocols that make up IoT.</p> <hr/> | | | |
| 3 | Explain the functionality of IOT network management sublayer. | [10] | CO1 | L2 |
| | <p>Access Network Sublayer-There is a direct relationship between the IoT network technology you choose and the type of connectivity topology this technology allows. Each technology was designed with a certain number of use cases in mind (what to connect, where to connect, how much data to transport at what interval and over what distance). These use cases determined the frequency band that was expected to be most suitable, the frame structure matching the expected data pattern (packet size and communication intervals), and the possible topologies that these use cases illustrate.</p> <p>One key parameter determining the choice of access technology is the range between the smart object and the information collector. List of some access technologies you may encounter in the IoT world and the expected transmission distances.</p> | | | |

Range estimates are grouped by category names that illustrate the environment or the vertical where data collection over that range is expected. Common groups are as follows:

PAN (personal area network): Scale of a few meters. This is the personal space around a person. A common wireless technology for this scale is Bluetooth.

HAN (home area network): Scale of a few tens of meters. At this scale, common wireless technologies for IoT include ZigBee and Bluetooth Low Energy (BLE).

NAN (neighborhood area network): Scale of a few hundreds of meters. The term NAN is often used to refer to a group of house units from which data is collected.

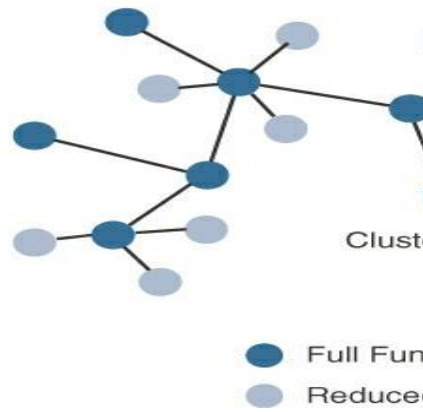

FAN (field area network): Scale of several tens of meters to several hundred meters. FAN typically refers to an outdoor area larger than a single group of house units. The FAN is often seen as “open space” (and therefore not secured and not controlled).

LAN (local area network): Scale of up to 100 m. This term is very common in networking, and it is therefore also commonly used in the IoT space when standard networking technologies (such as Ethernet or IEEE 802.11) are used.

Similar ranges also do not mean similar topologies. Some technologies offer flexible connectivity structure to extend communication possibilities:

Point-to-point topologies

Point-to-multipoin

| 4 | Explain the differences between IT and OT. Explain Edge, fog and cloud computing. | [10] | CO2 | L2 |
|---|---|------|-----|----|

Until recently, information technology (IT) and operational technology (OT) have for the most part lived in separate worlds. IT supports connections to the Internet along with related data and technology systems and is focused on the secure flow of data across an organization. OT monitors and controls devices and processes on physical operational systems. These systems include assembly lines, utility distribution networks, production facilities, roadway systems, and many more. Typically, IT did not get involved with the production and logistics of OT environments. Management of OT is tied to the lifeblood of a company. For example, if the network connecting the machines in a factory fails, the machines cannot function, and production may come to a standstill, negatively impacting business on the order of millions of dollars. On the other hand, if the email server (run by the IT department) fails for a few hours, it may irritate people, but it is unlikely to impact business at anywhere near the same level. **Table below highlights some of the differences between IT and OT networks and their various challenges.**

| Criterion | Industrial OT Network | Enterprise IT Network |
|---|---|--|
| Operational focus | Keep the business operating 24x7 | Manage the computers, data, and employee communication system in a secure way |
| Priorities | 1. Availability 2. Integrity 3. Security | 1. Security 2. Integrity 3. Availability |
| Types of data | Monitoring, control, and supervisory data | Voice, video, transactional, and bulk data |
| Security | Controlled physical access to devices | Devices and users authenticated to the network |
| Implication of failure | OT network disruption directly impacts business | Can be business impacting, depending on industry, but workarounds may be possible |
| Network upgrades (software or hardware) | Only during operational maintenance windows | Often requires an outage window when workers are not onsite; impact can be mitigated |
| Security vulnerability | Low: OT networks are isolated and often use proprietary protocols | High: continual patching of hosts is required, and the network is connected to Internet and requires vigilant protection |

| 5 | List and explain different types of sensors | [10] | CO2 | L2 |
|---|---|------|-----|----|

| | | | | |
|---|--|------|-----|----|
| 5 | <p>Sensors:</p> <ul style="list-style-type: none"> • A sensor does exactly as its name indicates: It senses. • A sensor measures some physical quantity and converts that measurement reading into a digital representation. • That digital representation is typically passed to another device for transformation into useful data that can be consumed by intelligent devices or humans. • Sensors are not limited to human-like sensory data. • They are able to provide an extremely wide spectrum of rich and diverse measurement data with far greater precision than human senses. • Sensors provide superhuman sensory capabilities. • Sensors can be readily embedded in any physical objects that are easily connected to the Internet by wired or wireless networks, they can interpret their environment and make intelligent decisions. <p>Sensors have been grouped into different categories</p> <ul style="list-style-type: none"> • Active or passive: Sensors can be categorized based on whether they produce an energy output and typically require an external power supply (active) or whether they simply receive energy and typically require no external power | [10] | CO2 | L2 |
|---|--|------|-----|----|

supply (passive).

- **Invasive or non-invasive:** Sensors can be categorized based on whether a sensor is part of the environment it is measuring (invasive) or external to it (non-invasive).
- **Contact or no-contact:** Sensors can be categorized based on whether they require physical contact with what they are measuring (contact) or not (no-contact).
- **Absolute or relative:** Sensors can be categorized based on whether they measure on an absolute scale (absolute) or based on a difference with a fixed or variable reference value (relative).
- **Area of application:** Sensors can be categorized based on the specific industry or vertical where they are being used.
- **How sensors measure:** Sensors can be categorized based on the physical mechanism used to measure sensory input (for example, thermoelectric, electrochemical, piezoresistive, optic, electric, fluid mechanic, photoelastic).
- **What sensors measure:** Sensors can be categorized based on their applications or what physical variables they measure.
The physical phenomenon a sensor is measuring.

| Sensor Types | Description | Examples |
|---------------------------|---|--|
| Position | A position sensor measures the position of an object; the position measurement can be either in absolute terms (absolute position sensor) or in relative terms (displacement sensor). Position sensors can be linear, angular, or multi-axis. | Potentiometer, inclinometer, proximity sensor |
| Occupancy and motion | Occupancy sensors detect the presence of people and animals in a surveillance area, while motion sensors detect movement of people and objects. The difference between the two is that occupancy sensors generate a signal even when a person is stationary, whereas motion sensors do not. | Electric eye, radar |
| Velocity and acceleration | Velocity (speed of motion) sensors may be linear or angular, indicating how fast an object moves along a straight line or how fast it rotates. Acceleration sensors measure changes in velocity. | Accelerometer, gyroscope |
| Force | Force sensors detect whether a physical force is applied and whether the magnitude of force is beyond a threshold. | Force gauge, viscometer, tactile sensor (touch sensor) |
| Pressure | Pressure sensors are related to force sensors, measuring force applied by liquids or gases. Pressure is measured in terms of force per unit area. | Barometer, Bourdon gauge, piezometer |
| Flow | Flow sensors detect the rate of fluid flow. They measure the volume (mass flow) or rate (flow velocity) of fluid that has passed through a system in a given period of time. | Anemometer, mass flow sensor, water meter |

| | | | | |
|---|---|------|-----|----|
| 6 | Define Smart object. Explain its characteristics. Explain the trends in smart objects impacting IoT. | [10] | CO2 | L2 |
| | <p>Smart objects are, quite simply, the building blocks of IoT. They are what transform everyday objects into a network of intelligent objects that are able to learn from and interact with their environment in a meaningful way.</p> <p>The term smart object, despite some semantic differences, is often used interchangeably with terms such as smart sensor, smart device, IoT device, intelligent device, thing, smart thing, intelligent node, intelligent thing, ubiquitous thing, and intelligent product.</p> <p>The following four defining characteristics</p> <ul style="list-style-type: none"> • Processing Unit: A smart object has some type of processing unit for acquiring data, processing and analysing sensing information received by the sensor(s), coordinating control signals to any actuators, and controlling a variety of functions on the smart object, including the communication and power systems. • Sensor(s) and /or actuator(s): A smart object is capable of interacting with the physical world through sensors and actuators. A smart object does not need to contain both sensors and actuators. In fact, a smart object can contain one or multiple sensors and/or actuators, depending upon the application. • Communication Device: The communication unit is responsible for connecting a smart object with other smart objects and the outside world (via the network). Communication devices for smart objects can be either wired or wireless. • Power Source: Smart objects have components that need to be powered. Interestingly, the most significant power consumption usually comes from the communication unit of a smart object. <p><u>The broad generalizations and trends impacting IoT are</u></p> <ul style="list-style-type: none"> • Size is decreasing: Some smart objects are so small they are not even visible to the naked eye. This reduced size makes smart objects easier to embed in everyday objects. • Power consumption is decreasing: The different hardware components of a smart object continually consume less power. Some battery-powered sensors last 10 or more years without battery replacement. • Processing power is increasing: Processors are continually getting more powerful and smaller. • Communication capabilities are improving: It's no big surprise that wireless speeds are continually increasing, but they are also increasing in range. IoT is driving the development of more and more specialized communication protocols covering a greater diversity of use cases and environments. • Communication is being increasingly standardized: There is a strong push in the industry to develop open standards for IoT communication protocols. In addition, there are more and more open source efforts to advance IoT. | | | |
