Answer Scheme & Model Solution- IAT1

Sub: Database Management System		Sub Code: 18CS53	Sem/Branch:	ch: V/CSE Section		Sections:	ns: A,B,C	
						MARKS	CO	RBT
Question	1	Define an entity and an at	tribute. Explain the d	lifferent types		10	CO1	L2
		of attributes that occur in	an ER model, with a	n example of				
		each with their correspond	ding ER notations					
Scheme		Define entity with example	le.			2		
		Define attribute with exar	nple.			2		
		Explain types with notation	on and example			6		
Solution		Entities and Attributes The basic object that the Elwith an independent existe example, a particular person existence (for instance, a concentration Attribute - the particular promay be described by the emposite versus multi-valued, and ston Composite versus Simple (Asubparts, which represent in Address attribute of the EM and Zip,3 with the values in not divisible are called simple for example, Street_address Number, Street, and Apartmath A composite attribute is represented at third person. One person is a person of values for the Computation of the Composite attribute is represented attribute in the Composite attribute in the Composite attribute is represented attribute in the Composite attribute in the Composit	ence. An entity may be a car, house, or emploympany, a job, or a universely properties that describe an exployee's name, age, addocur in the ER modered versus derived. Atomic) Attributes: Concore basic attributes we PLOYEE entity can be 2311 Kirby', 'Houstoned or atomic attributes of can be further subdivent_number, the explosion of the explosi	be an object we wee) or it may be ersity course). In entity. For exidress, salary, a del: simple ver mposite attribute ith independent esubdivided in in', 'Texas', and ided into three mass. Composite attribute ith independent in the existing of the subdivided in in', 'Texas', and ided into three mass. Most attribute valued. For example, therefore, different in the such attributer bounds to compare the such attributer bounds to compare it in as the such attributer bounds to compare it is such attributer bounds.	ampnd journal sussesses of the susses of the	a physical nobject with obe, an EMP ob. composite, an be divide earnings. For treet_addref 7001. Attractes can for aple composite, and the person people can are called main the number of the person ar	existence th a conce t	e (for eptual entity alued naller e, the State, at are rchy; outes:

Question	2	of Age can be determined from the current (today's) date and the Birth_date. The Age attribute is hence called a derived attribute and it the Birth_date attribute, which is called a stored attribute. A Derived attribute is represented in ER diagram as Simple, single and stored attributes are represented in ER diagram as Considering the following relation for a database of the company: Employee(Eno., Name,Salary,DoB,Dnumber) Department(Dnumber, Dname, MgrNo) DeptLocation(Dnumber, Dlocation) Write SQL statements for: i. Create a COMPANY database. ii. In COMPANY database create tables as given above. Ensure all the required constraints are enforced.			
		iii. Write insert statements to insert at least two rows in a table.			
Scheme		Create database statement Create table and alter statements with proper FK declaration Insert and update statements	1 5 4		
Solution		i) Create database COMPANY; use COMPANY;			•
		CREATE TABLE Employee(Eno int PRIMARY KEY, Name varchar(10), Salary int, DOB date, Dnumber int); CREATE TABLE Department(Dnumber int PRIMARY KEY, Dname varchar(10), Mgr_No int,			
Foreign key(Mgr_No) references Employee(Eno)); ALTER TABLE Employee ADD FOREIGN KEY(Dnumber) REFERENCES Department(Dnumber);					
		CREATE TABLE DeptLocation(Dnumber int, Dlocation varchar(10) PRIMARY KEY(Dnumber, Dlocation), Foreign key(Dnumber) references Department(Dnumber));			
		Insert into Employee(1,'A',10000,'01-01-2000',null); Insert into Employee(2,'B',20000,'11-11-2000',null);			
		Insert into Department(50,'X',1);			

		Insert into Department(51,'Y',2);			
		Update table Employee set Dnumber=50 where Eno=1; Update table Employee set Dnumber=51 where Eno=2; Insert into DeptLocation(50,'Banaglore'); Insert into DeptLocation(50,'Mysore'); Insert into DeptLocation(51,'Banaglore');			
Question	3	Design an ER diagram for an insurance company - Assume suitable entity types like CUSTOMER, AGENT, BRANCH, POLICY, PAYMENT and relationships between them.	10	CO1	L3
Scheme	•	Relevant Entities Relevant attributes Relevant relationships Relevant constraints Assumptions	2 2 2 2 2 2		
		Policy Id	1 AGEN Works 1 BRAN	T lie	rt year rrade
 The following are the assumptions made in this ER diagram: Customer name is assumed to be a composite attribute. A Customer must buy policies. A policy must have a customer. A policy must have a payment and a Payment must be associated with a policy. A Policy must belong to one branch and A branch will have several policies. An agent must work for at least one branch. A branch can have several agents but there can exist a branch without an agent associated with it. An agent can register several policies. A policy can be registered by an agent. 					
Question Scheme	4	Discuss database system environment with its component modules and their interactions with a neat diagram. Diagram Explanation	10 3 7	CO1	L2

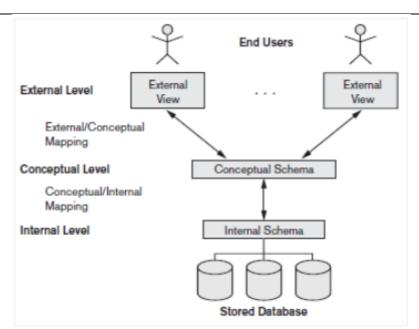

```
CREATE TABLE EMPLOYEE
      SSN NUMBER(10) PRIMARY KEY,
      NAME VARCHAR(10) NOT NULL
Unique: The UNIQUE Constraint prevents two records from having identical values in
a particular column. In the below example, the DBMS will not allow a row which tries
to insert duplicate value into the phone number field.
CREATE TABLE EMPLOYEE
      SSN NUMBER(10) PRIMARY KEY,
      NAME VARCHAR(10) NOT NULL,
      PHONE NUMBER(10) UNIQUE
Default: The DEFAULT constraint provides a default value to a column when the
INSERT INTO statement does not provide a specific value. In the below example, the
DBMS insert 10000 as a default value into Salary field for a row if no value is specified
while inserting that row.
CREATE TABLE EMPLOYEE
      SSN NUMBER(10) PRIMARY KEY,
      NAME VARCHAR(10) NOT NULL,
      PHONE NUMBER(10) UNIQUE,
      SALARY NUMBER(5) DEFAULT 10000
Primary Key: A primary key is a single field or combination of fields that uniquely
identify a record. The fields that are part of the primary key cannot contain a NULL
value and must be Unique. Each table should have a primary key, and each table can
have only ONE primary key. In the below example, SSN is a primary key, hence it must
be unique and not take null value and the table Employee cannot have any other
attribute as primary key as it already has SSN has PK.
CREATE TABLE EMPLOYEE
      SSN NUMBER(10) PRIMARY KEY,
      NAME VARCHAR(10) NOT NULL,
      PHONE NUMBER(10) UNIQUE,
      SALARY NUMBER(5) DEFAULT 10000
Foreign Key: A foreign key is a key used to link two tables together. Foreign Key is a
column or a combination of columns whose values match a Primary Key of another
table (parent table/referred table). The relationship between 2 rows of two tables
matches the Primary Key in one of the parent table with a Foreign Key value of the
referenced table. In the below table, DEPTNO is a foreign key referencing to DNO of
Department table. The DEPTNO attribute can take value which is present in DNO of
department table or NULL value.
CREATE TABLE EMPLOYEE
      SSN NUMBER(10) PRIMARY KEY,
      NAME VARCHAR(10) NOT NULL,
      PHONE NUMBER(10) UNIQUE,
      SALARY NUMBER(5) DEFAULT 10000
      DEPTNO NUMBER(2) REFERENCES DEPARTMENT(DNO)
)
Check Constraint: Check constraint is used to enforce a condition on an attribute in a
```

Check Constraint: Check constraint is used to enforce a condition on an attribute in a table. A record is inserted only if the check constraint is satisfied. If the constraint is not satisfied, the record insertion will be rejected.

CREATE TABLE EMPLOYEE

SSN NUMBER(10) PRIMARY KEY. NAME VARCHAR(10) NOT NULL. PHONE NUMBER(10) UNIQUE. AGE NUMBER(10) UNIQUE. AGE NUMBER(2) CHECK AGE-16. SALARY NUMBER(5) DEFAULT 1000. DEPTNO NUMBER(2) REFERENCES DEPARTMENT(DNO)) Cardinality ratio with example 2.5								
Question 6a Explain structural constraints of a relationship-type with 5 CO1 L2								
Salary NUMBER(3) DEFAULT 10000.								
DEPTNO NUMBER(2) REFERENCES DEPARTMENT(DNO)								
Cuestion Ga Explain structural constraints of a relationship-type with 5 CO1 L2								
Scheme Cardinality ratio with example Participation with example 2.5 Solution Cardinality ratio and participation constraints, taken together are the structural constraints of a relationship type. The cardinality ratio for a binary relationship specifies the maximum number of relationship instances that an entity can participate in. For example, consider a binary relationship type WORKS_FOR between Department and Employee entity types, DEPARTMENT:EMPLOYEE is of cardinality ratio 1:N, meaning that each department can be related to numerous employees, but an employee can be related to (work for) only one department. The possible cardinality ratios for binary relationship types are 1:1, 1:N, N:1, and M:N. Cardinality ratio 1:N of a relationship R between E1 & E2 entities is given as below in ER diagrams. E1 R N E2 The binary relationship MANAGES which relates a department entity to the employee who manages that department; the cardinality ratio is 1:1. This represents the constraint that an employee can manage only one department and that a department has only one manager. The relationship type WORKS_ON between Employee entity and the Project entity that he works for, is of cardinality ratio M:N, representing that an employee can into the works for, is of cardinality ratio M:N, representing that an employee can be related to another entity via the relationship type. Works and a project can have several employees. The participation constraint specifies whether the existence of an entity depends on its being related to another entity via the relationship type. There are two types of participation constraints—total and partial. If a company policy states that every employee must work for a department, then an employee entity can exist only if it participates in a WORKS_FOR relationship instance. Thus, the participation of EMPLOYEE in WORKS_FOR is called total participation, meaning that every entity in "the total set" of employee entities must be related to a department, so the participation of EMPLOYEE in the)

Thus, the participation of EMPLOYEE in WORKS_FOR is called total participation, meaning that every entity in "the total set" of employee entities must be related to a department entity via WORKS_FOR. Total participation is also called existence dependency. On the other hand, we do not expect every employee to manage a department, so the participation of EMPLOYEE in the MANAGES relationship type is partial, meaning that some or "part of the set of" employee entities are related to a department entity via MANAGES, but not necessarily all. In a relationship R, where participation of entity E1 is partial & participation of E2 is total, is represented in ER diagram as below,					
Scheme Diagram 2	Ouestion	6b	Explain three schema architecture with a neat diagram.	10	CO1	L2

			Explanation					

Solution

The three-schema architecture is a convenient tool with which the user can visualize the schema levels in a database system. The goal of the three-schema architecture, is to separate the user applications from the physical database. In this architecture, schemas can be defined at the following three levels:

- a) Internal Level: The internal level has an internal schema, which describes the physical storage structure of the database. The internal schema uses a physical data model and describes the complete details of data storage and access paths for the database.
- **b)** Conceptual level: The conceptual level has a conceptual schema, which describes the structure of the whole database for a community of users. The conceptual schema hides the details of physical storage structures and concentrates on describing entities, data types, relationships, user operations, and constraints. Usually, a representational data model is used to describe the conceptual schema when a database system is implemented. This implementation conceptual schema is often based on a conceptual schema design in a high-level data model.
- c) External or view level: The external or view level includes a number of external schemas or user views. Each external schema describes the part of the database that a particular user group is interested in and hides the rest of the database from that user group. As in the previous level, each external schema is typically implemented using a representational data model, possibly based on an external schema design in a high-level data model.

Mapping: The three schemas are only descriptions of data; the stored data that actually exists is at the physical level only. In a DBMS based on the three-schema architecture, each user group refers to its own external schema. Hence, the DBMS must transform a request specified on an external schema into a request against the conceptual schema, and then into a request on the internal schema for processing over the stored database. If the request is database retrieval, the data extracted from the stored database must be reformatted to match the user's external view. The processes of transforming requests and results between levels are called mappings.
